SOAP Note

Subjective

Patient reports 1-day history of frequent urination, dysuria, and cloudy malodorous urine. Mild lower abdominal discomfort noted. No fever, chills, or back/side pain.

Objective

Not documented

Assessment

Suspected uncomplicated urinary tract infection (UTI).

Plan

Arrange urine test to confirm UTI. If confirmed, prescribe appropriate antibiotics. Advise patient to complete full antibiotic course. Instruct patient to seek prompt medical care if fever, vomiting, or significant back pain develops.

Differential Diagnosis Suggestions

Supportive suggestions only; requires clinician verification and approval.

1. Uncomplicated lower urinary tract infection (cystitis) (77%)

Rationale: Patient presents with classic symptoms of lower UTI (cystitis) including dysuria, frequency, and cloudy malodorous urine. No systemic symptoms or complicating factors are present.

2. Asymptomatic bacteriuria (45%)

Rationale: Cloudy and malodorous urine could indicate bacteriuria, though patient's urinary symptoms make this less likely as primary diagnosis.

3. Vaginitis (in female patients) (37%)

Rationale: Dysuria can occur with vaginal infections, though other urinary symptoms are more suggestive of UTI. Patient gender not specified.

4. Urethritis (37%)

Rationale: Could cause dysuria but less likely given other urinary symptoms and absence of discharge or sexual risk factors mentioned.

5. Acute pyelonephritis (30%)

Rationale: No systemic symptoms (fever, chills, flank pain) present to suggest upper UTI. Included as important to rule out given potential complications.
